1. Stance phase

- ▶ Movement of the foot on the ground
- ▶ Foot moves backwards (respective to walking direction)
- ▶ Backwards movement forces the robot body to move forward

2. Swing phase

- ▶ Movement of the foot through free space without ground contact
- ▶ Foot moves forwards
- ▶ Start- and endpoint are on the ground for transition from and to stance movement

Swing trajectory constraints

- ▶ General swing phase constraints
 - ▶ Start position
 - ▶ End position

Swing trajectory constraints

- ▶ General swing phase constraints
 - ▶ Start position
 - ▶ End position
- ▶ Constraints due to the robot design
 - ▶ Working space for each joint of a leg
 - ▶ Minimal required swing height
 - ▶ Acceleration and speed of joint drives

Swing trajectory constraints

- ▶ General swing phase constraints
 - ▶ Start position
 - ▶ End position
- ▶ Constraints due to the robot design
 - ▶ Working space for each joint of a leg
 - ▶ Minimal required swing height
 - ▶ Acceleration and speed of joint drives
- ▶ Environmental constraints
 - ▶ Position and size of obstacles

Trajectory planning methods – Global approaches I

▶ Roadmap

- ▶ Corners of obstacles are connected by straight lines to form the shortest path along the obstacles
- ▶ Obstacles must be known as polygons

▶ Cell decomposition

- ▶ Free space divided into cells
 - ▶ Exact decomposition
 - ▶ Approximate decomposition
- ▶ Obstacles must be known
- ▶ Neighbouring cells are represented in a graph
- ▶ A path in the graph represents one possible trajectory

Trajectory planning methods – Global approaches II

- ▶ Potential field
 - ▶ Free space is discretized in a mesh
 - ▶ Obstacle points and start point are weighted repelling
 - ▶ Goal point is weighted attracting
 - ▶ Trajectory is defined by a gradient descent
 - ▶ Problem of getting trapped in local minima
 - ▶ Obstacles must be known

Trajectory planning methods – Local approaches

- ▶ Self defined trajectory
- ▶ Selecting additional constraints (e.g. approach angle)
- ▶ Defining via points
- ▶ Connecting via points by different methods
 - ▶ Linear
 - ▶ Linear with parabolic blends
 - ▶ (Cubic) splines (*one proposed approach by zeng*)
 - ▶ Elliptic (*approach used by **paskarbeit** on HECTOR*)
- ▶ Collisions with obstacles must be handled or avoided

Deciding for one approach

- ▶ In order to implement a trajectory generator one of these methods has to be chosen
- ▶ This decision is highly dependent on the robot it has to generate trajectories for
- ▶ If the robot has a notion of its surrounding space, a global approach is possible
- ▶ Otherwise a local approach has to be used and collisions have to be handled
- ▶ Since the global approaches use a discretisation of the space and therefore have to compute many possible paths to choose one for each step
- ▶ Using a naive local approach requires little computation and allows reuse of a path
- ▶ A notion of the surrounding space in combination with a local approach can be used to minimize collisions by choosing optimal goal positions
